

CASE : English Proficiency for Students with English as Foreign Language.

The final course grades for a given English proficiency course are believed to be approximately normal distributed with mean 2.7 and standard deviation 0.5.

A sample of students with *English as Foreign Language* obtained the following grades.

0.7 3.5 2.5 3.1 1.8 2.6 3.8 1.1

1.1 2.6 1.9 2.9 3.6 2.0 3.1 2.5

Is there reason to believe that these students do worse (or better) than their fellow American students?

CASE : English Proficiency for Students with English as Foreign Language.

0.7	3.5	2.5	3.1	1.8	2.6	3.8	1.1	$\bar{x} = 2.425$ $s = 0.93$
1.1	2.6	1.9	2.9	3.6	2.0	3.1	2.5	

Small Sample Inference Procedures when σ is unknown.

- For **small samples** (say $n < 30$), we must use a more exact distribution for the test statistic under the null-hypothesis:

Test Statistic:

$$t = \frac{\bar{x} - \mu_0}{s / \sqrt{n}} \sim t(\text{df})$$

$1-\alpha$ Confidence Interval:

$$\bar{x} \pm t^* \frac{s}{\sqrt{n}}$$

Student's t -Distribution

Degrees of Freedom, df : A parameter that identifies each different distribution of Student's t -distribution. For the methods presented in this chapter, the value of df will be the sample size minus 1, $df = n - 1$.

Student's t -Statistic

1. When s is used as an estimate for σ , the test statistic has two sources of variation: \bar{x} and s

2. The resulting test statistic:

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

is known as the **Student's t -statistic** with $n-1$ degrees of freedom

3. Assumption: samples are taken from normal populations
4. The population standard deviation, σ , is almost never known in real-world problems

The standard error will almost always be estimated using s/\sqrt{n}

Almost all real-world inference about the population mean will be completed using the Student's t -statistic

Table D:
Used for finding t^* critical values

Table entry for p and C is the critical value t^* with probability p lying to its right and probability C lying between $-t^*$ and t^* .

Experiments

PRINCIPLES OF EXPERIMENTAL DESIGN

The basic principles of statistical design of experiments are

1. **Compare** two or more treatments. This will control the effects of lurking variables on the response.
2. **Randomize**—use impersonal chance to assign experimental units to treatments.
3. **Repeat** each treatment on many units to reduce chance variation in the results.

Independent Samples vs. Matched Pairs

- 200 customers who bought softdrinks in a supermarket, were selected to participate in the study.
- 100 participants were selected at random to drink a can of “PEPSI”, and the other 100 a can of “COCA-COLA” and each participant would rate the drink on a scale [P, F, G, E].

Independent Samples vs. Matched Pairs

- 100 customers who bought softdrinks in a supermarket, were selected to participate in the study.
- The 100 participants were each given both a can of “PEPSI”, and a can of “COCA-COLA” (50 of them in reversed order) and each participant would rate each drink on a scale [P, F, G, E].

Independent Samples vs. Matched Pairs

The following situations all require inference about a mean or means. Identify each as (1) a single sample, (2) matched pairs, or (3) two independent samples.

- An education researcher wants to learn whether inserting questions before or after introducing a new concept in an elementary school mathematics text is more effective. He prepares two text segments that teach the concept, one with motivating questions before and the other with review questions after. Each text segment is used to teach a group of children, and their scores on a test over the material are compared.
- Another researcher approaches the same problem differently. She prepares text segments on two unrelated topics. Each segment comes in two versions, one with questions before and the other with questions after. Each of a group of children is taught both topics, one (chosen at random) with questions before and the other with questions after. Each child's test scores on the two topics are compared to see which topic he or she learned better.

Independent Samples vs. Matched Pairs

- To evaluate a new analytical method, a chemist obtains a reference specimen of known concentration from the National Institute of Standards and Technology. She then makes 20 measurements of the concentration of this specimen with the new method and checks for bias by comparing the mean result with the known concentration.
- Another chemist is evaluating the same new method. He has no reference specimen, but a familiar analytic method is available. He wants to know if the new and old methods agree. He takes a specimen of unknown concentration and measures the concentration 10 times with the new method and 10 times with the old method.

CASE : Durability of Jogging Shoes

- In an experiment 10 joggers were asked to test two different brands (A and B) of jogging shoes.
- Does the data indicate a difference between the durability of the two brands?

Jogger Brand	1	2	3	4	5	6	7	8	9	10
A	27	35	19	39	34	32	15	26	18	17
B	23	28	16	31	38	30	17	22	15	16

Number of durable weeks

CASE : Durability of Jogging Shoes

Jogger Brand	1	2	3	4	5	6	7	8	9	10
A	27	35	19	39	34	32	15	26	18	17
B	23	28	16	31	38	30	17	22	15	16
